## **The transmembrane protein Macroglobulin complement-related is essential for septate junction formation and epithelial barrier function in *Drosophila***

Batz, T ; Forster, D ; Luschnig, S

**Abstract:** Occluding cell-cell junctions in epithelia form physical barriers that separate different membrane domains, restrict paracellular diffusion and prevent pathogens from spreading across tissues. In invertebrates, these functions are provided by septate junctions (SJs), the functional equivalent of vertebrate tight junctions. How the diverse functions of SJs are integrated and modulated in a multiprotein complex is not clear, and many SJ components are still unknown. Here we report the identification of Macroglobulin complement-related (Mcr), a member of the conserved  $\alpha$ 2-macroglobulin ( $\alpha$ 2M) complement protein family, as a novel SJ-associated protein in *Drosophila*. Whereas  $\alpha$ 2M complement proteins are generally known as secreted factors that bind to surfaces of pathogens and target them for phagocytic uptake, Mcr represents an unusual  $\alpha$ 2M protein with a predicted transmembrane domain. We show that Mcr protein localizes to lateral membranes of epithelial cells, where its distribution overlaps with SJs. Several SJ components are required for the correct localization of Mcr. Conversely, Mcr is required in a cell-autonomous fashion for the correct membrane localization of SJ components, indicating that membrane-bound rather than secreted Mcr isoforms are involved in SJ formation. Finally, we show that loss of Mcr function leads to morphological, ultrastructural and epithelial barrier defects resembling mutants lacking SJ components. Our results, along with previous findings on the role of Mcr in phagocytosis, suggest that Mcr plays dual roles in epithelial barrier formation and innate immunity. Thus, Mcr represents a novel paradigm for investigating functional links between occluding junction formation and pathogen defense mechanisms.

## RESEARCH ARTICLE

# The transmembrane protein Macroglobulin complement-related is essential for septate junction formation and epithelial barrier function in *Drosophila*

Tilman Bätz<sup>‡</sup>, Dominique Förster<sup>\*‡</sup> and Stefan Lüschnig<sup>§</sup>**ABSTRACT**

Occluding cell-cell junctions in epithelia form physical barriers that separate different membrane domains, restrict paracellular diffusion and prevent pathogens from spreading across tissues. In invertebrates, these functions are provided by septate junctions (SJs), the functional equivalent of vertebrate tight junctions. How the diverse functions of SJs are integrated and modulated in a multiprotein complex is not clear, and many SJ components are still unknown. Here we report the identification of Macroglobulin complement-related (Mcr), a member of the conserved  $\alpha$ -2-macroglobulin ( $\alpha$ 2M) complement protein family, as a novel SJ-associated protein in *Drosophila*. Whereas  $\alpha$ 2M complement proteins are generally known as secreted factors that bind to surfaces of pathogens and target them for phagocytic uptake, Mcr represents an unusual  $\alpha$ 2M protein with a predicted transmembrane domain. We show that Mcr protein localizes to lateral membranes of epithelial cells, where its distribution overlaps with SJs. Several SJ components are required for the correct localization of Mcr. Conversely, Mcr is required in a cell-autonomous fashion for the correct membrane localization of SJ components, indicating that membrane-bound rather than secreted Mcr isoforms are involved in SJ formation. Finally, we show that loss of *Mcr* function leads to morphological, ultrastructural and epithelial barrier defects resembling mutants lacking SJ components. Our results, along with previous findings on the role of Mcr in phagocytosis, suggest that Mcr plays dual roles in epithelial barrier formation and innate immunity. Thus, Mcr represents a novel paradigm for investigating functional links between occluding junction formation and pathogen defense mechanisms.

**INTRODUCTION**

Epithelia form tissue barriers that separate functional compartments in organs. Occluding cell-cell junctions, which constrain the flow of solutes across the paracellular space, provide the epithelial diffusion barrier function. In vertebrates, tight junctions (TJs) form a seal between adjacent cells, thus providing a physical barrier that separates different membrane domains, restricts paracellular flux and

prevents pathogens from crossing epithelia (reviewed by Shin et al., 2006). In invertebrates, septate junctions (SJs) represent the functional equivalent of vertebrate TJs. SJs and TJs differ in their ultrastructure, subcellular localization and molecular composition. However, both types of occluding junctions contain four-transmembrane-domain proteins of the Claudin family at the core of the barrier-forming complex (Behr et al., 2003; Hemphälä et al., 2003; Paul et al., 2003). In vertebrates, the paranodal junctions between axons and glia cells (axo-glial septate junctions, or AGSJs) resemble the ultrastructure and molecular composition of invertebrate SJs, suggesting that SJs originated early during metazoan evolution and have been functionally conserved (Hortsch and Margolis, 2003; Banerjee et al., 2006). In invertebrates, SJs between glial cells provide the functional equivalent of the vertebrate blood-brain barrier (Carlson et al., 2000). Furthermore, SJs were shown to contribute to the immune barrier in the gut (Bonnay et al., 2013).

Although SJs and AGSJs have been intensely studied, many questions about their molecular components and their mechanism of assembly remain open. SJs are large multiprotein complexes containing cytoplasmic and integral membrane proteins, several of which were identified through genetic screens in *Drosophila* (reviewed by Wu and Beitel, 2004; Furuse and Tsukita, 2006; Banerjee et al., 2008). Two distinct subtypes of SJs are known: pleated SJs (pSJs) are found in ectodermal organs (epidermis, salivary glands, foregut, hindgut, tracheal system), whereas the ultrastructurally distinct smooth SJs (sSJs) form epithelial barriers in endodermal organs, such as the midgut (Tepass and Hartenstein, 1994). SJs are also essential for limiting the expansion of tracheal tubes during embryogenesis (Behr et al., 2003; Hemphälä et al., 2003; Paul et al., 2003), thus providing a phenotypic readout that enabled the identification of additional SJ components (Beitel and Krasnow, 2000). Interestingly, the barrier-forming and tube size-limiting functions of SJs are genetically separable, suggesting that SJs play multiple roles in epithelial morphogenesis and barrier formation (Paul et al., 2007). SJs are required for the accumulation of the secreted chitin deacetylases Serpentine (Serp) and Vermiform (Verm) in the tracheal lumen, where these proteins are required for limiting tube expansion, presumably through modifying a chitin matrix (Lüschnig et al., 2006; Wang et al., 2006). In addition, SJ-associated basolateral polarity proteins of the Scribble (Scrib)/Discs large 1 (Dlg)/Lethal (2) giant larvae (Lgl) complex limit tracheal tube elongation by restricting Crumbs (Crb)-dependent apical membrane expansion (Laprise et al., 2010). Despite these advances, the precise role of SJs in tracheal tube size control is not clear yet. Furthermore, it is not known how the diverse functions of SJs are integrated and modulated in different tissues and under different physiological conditions. Recent genetic and proteomic studies suggest that many SJ-associated proteins remain to be identified

(Hijazi et al., 2009; Nilton et al., 2010; Tiklová et al., 2010; Syed et al., 2011; Ile et al., 2012; Jaspers et al., 2012; Bonnay et al., 2013).

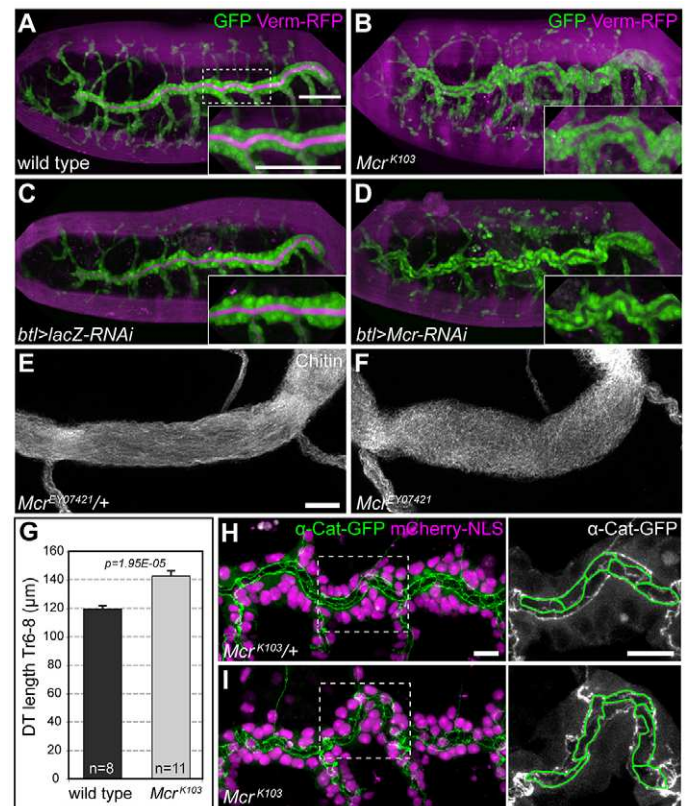

We identified Macroglobulin complement-related (*Mcr*) as a new SJ-associated protein. *Mcr* is a member of the widely conserved thioester protein (TEP) family, which includes  $\alpha$ -2-macroglobulin ( $\alpha$ 2M) and complement proteins as key factors in innate immunity (Nonaka and Yoshizaki, 2004). These proteins contain a highly reactive intrachain thioester bond that mediates covalent binding to pathogen surfaces or to proteases.  $\alpha$ 2M, the most abundant serum protein in human blood, acts as an antiprotease that inactivates a broad spectrum of proteases. Upon proteolytic cleavage of a 'bait' region,  $\alpha$ 2M undergoes a conformational change and covalently binds the attacking protease to the exposed thioester (Borth, 1992). The  $\alpha$ 2M-protease complex is subsequently cleared by receptor-mediated endocytosis. Complement factors participate in opsonization of pathogens, targeting them for phagocytosis or lysis. Insect TEPs were first studied in *Drosophila melanogaster* and *Anopheles gambiae* and are involved in the response to pathogens and parasites, most notably *Plasmodium* (Lagueux et al., 2000; Levashina et al., 2001). *Drosophila* contains six TEP family members, four of which (Tep1-4) are predicted secreted proteins expressed in hemocytes and thought to play roles in innate immunity (Lagueux et al., 2000; Bou Aoun et al., 2011). *Tep5* appears to be a pseudogene in *Drosophila melanogaster* (Bou Aoun et al., 2011). *Mcr* (Tep6) is a diverged TEP family member with a mutated thioester motif and a predicted transmembrane domain not found in other TEPs, suggesting that the functions of *Mcr* are distinct from those of other TEPs. *Mcr* binds to the surface of *Candida albicans* cells and targets them for phagocytic uptake by cultured *Drosophila* S2 cells, thus resembling the opsonizing effect of  $\alpha$ 2M in vertebrates (Stroschein-Stevenson et al., 2006). However, it is not yet clear whether *Mcr* plays a similar role in pathogen clearance *in vivo*.

We report here a new and surprising role of *Mcr* in SJ-dependent epithelial barrier formation. We show that *Mcr* protein localizes to the lateral membranes of epithelial cells, where its distribution overlaps with known SJ components. *Mcr* is required in a cell-autonomous fashion for the correct localization of SJ components, indicating that membrane-bound rather than secreted *Mcr* isoforms are involved in SJ formation. Finally, *Mcr* is essential for SJ-dependent tracheal tube size control and epithelial barrier function. Our results, along with previous work (Stroschein-Stevenson et al., 2006), suggest that *Mcr* plays dual roles in epithelial barrier formation and innate immunity. These findings call attention to a potential link between pathogen defense mechanisms and the structure of occluding cell-cell junctions in epithelia.

## RESULTS

### A new gene required for tracheal tube length control

In a mutagenesis screen for genes involved in tracheal tube size control we isolated a complementation group with five lethal alleles showing overelongated tortuous tracheae (Fig. 1A,B; supplementary material Fig. S1). We named the locus *lufischlange* (*luf*). Four *luf* alleles (*luf*<sup>D13</sup>, *luf*<sup>G249</sup>, *luf*<sup>K101</sup>, *luf*<sup>K103</sup>) were embryonic lethal, whereas one allele (*luf*<sup>H125</sup>) showed weaker tracheal phenotypes and was larval lethal. The amorphic allele *luf*<sup>K103</sup> was used for most analyses. The tracheal dorsal trunk (DT) in stage 16 *luf*<sup>K103</sup> embryos was 20% longer than that of controls (DT metamer 6-8; Fig. 1G). This effect was not due to an increase in tracheal cell number, which was unchanged in *luf* embryos (data not shown). Instead, the apical surfaces of DT cells in *luf* embryos were axially longer compared with controls, suggesting that abnormal cell shapes caused the overelongated tracheal phenotype in *luf* embryos (Fig. 1H,I). In

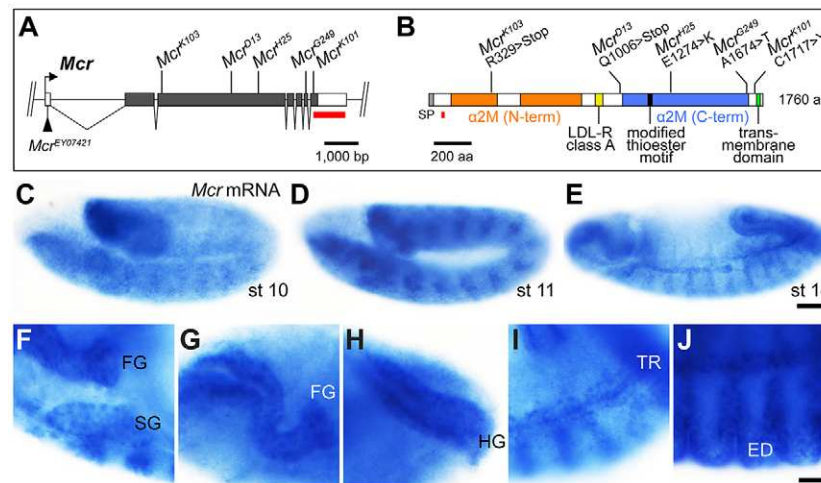

**Fig. 1. *Mcr* is required to limit tracheal tube length and luminal protein accumulation.** (A-D) Living stage 15 *Drosophila* embryos expressing cytoplasmic GFP (green) and secreted Verm-RFP (magenta) in tracheal cells controlled by *btl-Gal4*. *Mcr* mutations (B) or tracheal-specific expression of *Mcr* dsRNA (D) lead to overelongated tracheae compared with wild-type (A) or RNAi control (C) embryos. Note that Verm-RFP accumulates in tracheal lumina in wild-type and RNAi control embryos, whereas *Mcr* mutants and *Mcr* dsRNA-expressing embryos show reduced luminal Verm-RFP levels. Insets show magnifications of the boxed region in A. (E,F) Luminal chitin in fixed stage 15 embryos is organized into parallel fibrils in heterozygous *Mcr* control embryos (E), whereas the surface of the chitin cylinder is irregular and fibrils are disordered in *Mcr*<sup>EY07421</sup> mutants (F). (G) Quantification of dorsal trunk luminal length in tracheal metamer 6-8 in wild-type and *Mcr*<sup>K103</sup> mutant embryos. Error bars indicate s.e.m. (H,I) Tracheal metamer 6-8 in living stage 15 wild-type and *Mcr*<sup>K103</sup> embryos expressing  $\alpha$ -Cat-GFP and mCherry-NLS to label adherens junctions and nuclei in tracheal cells. Magnifications to the right show apical outlines of cells in metamer 7 highlighted in green. Note the abnormal elongation of apical cell surfaces along the tube axis in the *Mcr* mutant. DT, dorsal trunk. Scale bars: 50  $\mu$ m in A-D; 5  $\mu$ m in E,F; 10  $\mu$ m in H,I.

addition, *luf* mutants showed markedly reduced levels of Verm-RFP protein in the tracheal lumen (Fig. 1B; supplementary material Fig. S1), although the total amount of Verm-RFP detectable in embryonic extracts by immunoblot was unchanged (supplementary material Fig. S2). Furthermore, luminal chitin fibrils, which run parallel to the tube axis in the wild type, appeared disordered in *luf* mutants (Fig. 1E,F). Altogether, the morphological defects in *luf* embryos were reminiscent of mutants lacking SJ components (Behr et al., 2003; Wu and Beitel, 2004; Wu et al., 2004; Wang et al., 2006).

### *luf* is allelic to the *Mcr* locus

We mapped the *luf* locus to the cytological interval 28E1-E5. Within this interval, a lethal *P*-element insertion (*Mcr*<sup>EY07421</sup>; Fig. 2A) (Bellen et al., 2004) in the 5'UTR of the *Mcr* gene failed to complement all five *luf* alleles. Embryos carrying *Mcr*<sup>EY07421</sup> in *trans*

**Fig. 2. *Mcr* is expressed in embryonic epithelial tissues.** (A) Organization of the *Mcr* locus. Exons are shown as boxes with coding regions filled in black. Positions of EMS-induced mutations are indicated. *Mcr*<sup>EY07421</sup> is a P-element insertion in the 5'UTR of *Mcr*. The probe used for *in situ* hybridization is shown as a red bar. (B) Domain organization of *Mcr* protein. The signal peptide (SP), the N- and C-terminal  $\alpha$ -2-macroglobulin ( $\alpha$ 2M) domains, the LDL receptor class A domain, the modified thioester motif, and the transmembrane domain are shown. *Mcr* mutations are indicated. The anti-*Mcr* antiserum (Stroschein-Stevenson et al., 2006) was raised against a peptide indicated by the red bar. (C) *In situ* hybridization with an *Mcr* antisense probe shows the embryonic expression pattern of *Mcr* mRNA. Developmental stage is indicated. Zygotic *Mcr* transcripts are first detectable at stage 10 in the hindgut and foregut regions. From stage 11 onwards, *Mcr* is expressed in salivary gland, tracheal and epidermal cells. Controls with a sense probe gave no comparable signals (data not shown). (F-J) Magnifications of stage 14 embryos showing *Mcr* expression in foregut (FG), salivary gland (SG), hindgut (HG), tracheal (TR) and epidermal (ED) cells. Scale bars: 50  $\mu$ m in C-E; 20  $\mu$ m in F-J.

to the *luf* alleles showed the *luf* tracheal phenotype (data not shown), indicating that *luf* is allelic to *Mcr*. Furthermore, tracheal-specific expression of *Mcr* dsRNA resulted in overelongated tubes resembling those associated with *luf* alleles (Fig. 1C,D). Together, these findings indicate that *Mcr* function is required in tracheal cells for limiting tube length and for luminal accumulation of Verm-RFP.

*Mcr* encodes a protein of 1760 amino acids with a predicted molecular weight of 203 kDa. It contains an N-terminal signal peptide sequence, a large extracellular part, a transmembrane domain, and a short cytoplasmic domain of 15 amino acids (Fig. 2B). The extracellular part resembles TEP/ $\alpha$ 2M family proteins with N- and C-terminal  $\alpha$ -macroglobulin domains and a low-density lipoprotein receptor class A (LDLa) motif. The canonical thioester motif is mutated in *Mcr*, suggesting that *Mcr* does not function as a protease inhibitor (Stroschein-Stevenson et al., 2006; Bou Aoun et al., 2011). In addition, *Mcr* contains a predicted C-terminal transmembrane domain not found in other TEPs. The modified thioester motif and the transmembrane domain are conserved in insect *Mcr*/Tep6 homologs (Blandin and Levashina, 2004; Bou Aoun et al., 2011). Thus, *Mcr* represents a diverged member of the TEP family.

#### EMS-induced *Mcr* alleles carry point mutations affecting *Mcr* protein

*Mcr*<sup>K103</sup> and *Mcr*<sup>D13</sup> are amorphic alleles (data not shown) and contain premature stop codons predicted to result in truncated proteins of 329 and 1006 amino acids, respectively (Fig. 2A,B). Bands of the expected sizes (35 kDa and 130 kDa) were detectable in extracts from *Mcr*<sup>K103</sup> and *Mcr*<sup>D13</sup> embryos, respectively (supplementary material Fig S2). The remaining three alleles (*Mcr*<sup>H25</sup>, *Mcr*<sup>K101</sup> and *Mcr*<sup>G249</sup>) carry missense mutations at residues that are conserved among insect *Mcr*/Tep6 homologs (Fig. 2B). The hypomorphic allele *Mcr*<sup>H25</sup> contains a glutamate-to-lysine exchange at position 1274 inside the  $\alpha$ -macroglobulin complement component domain. *Mcr*<sup>K101</sup> contains a cysteine-to-tyrosine exchange at position 1717 N-terminal to the transmembrane domain. *Mcr*<sup>G249</sup> contains an

alanine-to-threonine exchange at position 1674 inside the  $\alpha$ -macroglobulin receptor-binding domain. The amounts and electrophoretic mobility of *Mcr* proteins were unchanged in *Mcr*<sup>H25</sup>, *Mcr*<sup>K101</sup> and *Mcr*<sup>G249</sup> embryos (supplementary material Fig. S2), suggesting that the missense mutations in these alleles affect *Mcr* protein function or localization.

#### *Mcr* is expressed in ectodermal epithelial tissues

We analyzed the expression pattern of *Mcr* mRNA during embryogenesis by *in situ* hybridization. *Mcr* mRNA was expressed in epithelial tissues from embryonic stage 10 [5 hours after egg lay (AEL)] onwards (Fig. 2C-E). *Mcr* transcripts were first detectable in the hindgut and epidermis and subsequently in the tracheal pits at stage 11 (9 hours AEL). During later embryonic stages, *Mcr* mRNA was found in the epidermis, tracheal system, foregut, hindgut and salivary glands (Fig. 2F-J), but not in the endodermal midgut. Thus, *Mcr* is selectively expressed in ectodermal epithelial tissues.

To study the distribution of *Mcr* protein we used an antiserum raised against a peptide located near the N-terminus after the signal sequence (Stroschein-Stevenson et al., 2006). On immunoblots, a band of ~210 kDa corresponding to full-length *Mcr* protein was detected throughout embryogenesis (supplementary material Fig. S3). This band was present in syncytial blastoderm embryos (0–1 hour AEL), indicating the presence of maternal *Mcr* gene products in the egg. *Mcr* protein levels increased during germ band extension (6 hours AEL) and continued to rise until the end of embryogenesis. As the levels of full-length *Mcr* protein increased, several bands of lower molecular weight appeared, which might represent degradation products or processed forms of *Mcr* protein (supplementary material Fig. S3).

#### *Mcr* protein localizes at the lateral plasma membrane of epithelial cells

*Mcr* protein was detectable in embryonic epithelia from germ band extension onwards (supplementary material Fig. S3). *Mcr* protein

**Fig. 3. Mcr protein localizes to lateral membranes of epithelial cells.** (A) Confocal sections of embryonic stage 16 salivary glands immunostained for Mcr, Uninflated (Uif; apical membrane), E-Cadherin (E-Cad; adherens junctions) and alpha-Spectrin ( $\alpha$ -Spec; Spectrin network below basolateral membrane). Mcr localizes to apicolateral and apical plasma membranes. (B-D) Confocal sections of stage 16 salivary gland (B), tracheal (C) and epidermal (D) cells immunostained for Mcr and Cora. Chitin (cyan) in C indicates the tracheal lumen. Mcr overlaps with Cora at lateral membranes, but extends further apically than Cora (arrowheads in C). Lower panels in D show an orthogonal transverse section of the boxed region in D. (E) Mcr localizes at germ cell membranes in embryonic gonads. Mcr- and Cora-expressing tracheal cells flank the gonad, which does not express Cora. (F) Mcr localizes to the plasma membrane and to intracellular puncta in transfected S2R+ cells expressing an *Mcr* cDNA. Note that Mcr protein is not detectable in non-transfected cells. Scale bars: 5  $\mu$ m.

was enriched on lateral cell membranes of salivary gland, epidermis, tracheal and hindgut epithelial cells (Fig. 3). Double labeling with alpha-Spectrin to outline lateral cell boundaries indicated that Mcr levels are highest in the apical third of the lateral membrane (Fig. 3A). As this distribution was reminiscent of SJ components, we analyzed the localization of Mcr relative to SJ proteins. Mcr signals overlapped with the SJ-associated cytoplasmic ERM (Ezrin, Radixin and Moesin) protein Coracle (Cora) (Fehon et al., 1994) in salivary gland, epidermal and tracheal cells (Fig. 3B-D). However, in all cell types Mcr signals extended slightly further apically than Cora signals. In salivary glands, Mcr lined the apical cell surfaces facing the lumen, in addition to its distribution on lateral membranes (Fig. 3B). Mcr protein was also present on lateral cell membranes in larval imaginal discs, as well as in larval and adult trachea, foregut and hindgut, but not in the midgut and Malpighian tubules (data not shown). Interestingly, besides epithelial cells, we found Mcr protein also at the plasma membrane of embryonic germ cells and adult spermatocytes, which do not exhibit epithelial features such as SJs (Fig. 3E; data not shown). Consistent with previous work (Stroschein-Stevenson et al., 2006), we did not detect Mcr protein in cultured S2 cells. However, upon transient transfection of an *Mcr* cDNA, Mcr protein was detectable at the plasma membrane, as well as in intracellular puncta in S2 cells (Fig. 3F). Surprisingly, although *Mcr* is expressed in larval hemocytes (Bou Aoun et al., 2011), we were unable to detect *Mcr* transcripts and Mcr protein in embryonic hemocytes (data not shown). Taken together, Mcr is an unusual TEP that localizes to lateral membranes of ectodermal epithelial cells and to the plasma membrane of germ cells.

We analyzed the subcellular distribution of Mcr protein in the five mutant alleles in epidermis, salivary gland, hindgut, tracheal and germ cells (supplementary material Fig. S4). Mcr signals were abolished in *Mcr*<sup>K103</sup> embryos and only residual signal was detectable in *Mcr*<sup>D13</sup> embryos. By contrast, Mcr levels in the hypomorphic allele *Mcr*<sup>H25</sup> and in the strong allele *Mcr*<sup>K101</sup> were comparable to those of wild-type embryos. However, in both of these mutants Mcr protein was mislocalized basolaterally in salivary gland and hindgut cells. In *Mcr*<sup>G249</sup> embryos, membrane localization of Mcr was lost and the protein instead accumulated intracellularly (supplementary material Fig. S4D). These findings suggest that correct membrane localization of Mcr protein, presumably mediated by the predicted transmembrane domain, is essential for Mcr function.

#### Localization of SJ components depends on Mcr

The *Mcr* mutant phenotype and the localization of Mcr protein suggested that Mcr is involved in the assembly or maintenance of SJs. Mutations in SJ components lead to mislocalization of other SJ proteins and to breakdown of the entire complex (Ward et al., 1998; Genova and Fehon, 2003). We therefore examined the localization of the cytoplasmic SJ components Cora, Dlg (Woods and Bryant, 1991) and Scrib (Bilder and Perrimon, 2000) and of the membrane proteins Fasciclin III (FasIII) (Snow et al., 1989), Neurexin IV (Nrx-IV) (Baumgartner et al., 1996) and Neuroglian (Nrg) (Genova and Fehon, 2003) in salivary gland, tracheal, epidermal and hindgut cells of *Mcr*<sup>K103</sup> embryos (Fig. 4; data not shown). The distribution of all SJ components tested was affected in *Mcr* embryos. The apicolateral accumulation of Cora and FasIII

**Fig. 4. *Mcr* is essential for the correct localization of SJ components.** (A-G) Confocal sections of salivary glands in fixed (A-D) and living (E-G) stage 15 embryos. In *Mcr*<sup>K103</sup> heterozygous control embryos (upper rows), Cora (B), Dlg (C), FasIII (D), Scrib-GFP (E), NrX-IV-GFP (F) and Nrg-YFP (G) are localized at the level of SJs in the apicolateral membrane. In *Mcr*<sup>K103</sup> mutants (lower rows), in which *Mcr* protein is not detectable (A), the localization of Cora, Dlg, FasIII, Scrib-GFP and NrX-IV-GFP extends basally and enrichment of these proteins at SJs is reduced or lost. Nrg-YFP is completely absent from lateral membranes in *Mcr*<sup>K103</sup> embryos, whereas the apically localized pool (arrowheads) of Nrg-YFP increases in *Mcr*<sup>K103</sup> mutants. (G') Low-magnification projection of the salivary gland in G. Scale bars: 5 μm in A-G; 10 μm in G'.

was lost and the distribution of these proteins extended along the entire lateral membrane (Fig. 4B,D). Similarly, Dlg, Scrib-GFP and NrX-IV-GFP were mislocalized basolaterally in *Mcr*<sup>K103</sup> embryos, although these proteins were still partially enriched in the apicolateral zone (Fig. 4C,E,F). By contrast, Nrg-YFP was completely lost from lateral membranes of all epithelia in *Mcr*<sup>K103</sup> embryos (Fig. 4G). Interestingly, a fraction of Nrg-YFP localizes at the apical membrane in wild-type salivary glands (Fig. 4G,G'). In *Mcr* mutants, this apical pool of Nrg-YFP appeared increased at the expense of basolateral Nrg-YFP, suggesting that Nrg-YFP redistributes in the absence of *Mcr* function and that *Mcr* is required to maintain Nrg at basolateral, but not at apical, membranes. Membrane localization of Nrg-YFP was rescued by the expression of a UAS-*Mcr* construct in epidermal stripes in *Mcr* mutant embryos (Fig. 5). Although the overexpressed *Mcr* protein was partially retained intracellularly, a fraction of the protein accumulated at the plasma membrane. Importantly, *Mcr* protein did not spread away from the producing cells (Fig. 5B) and Nrg-YFP membrane localization was restored only in the *Mcr*-expressing cells, but not in cells between the *Mcr*-expressing stripes (Fig. 5C), indicating that *Mcr* functions in a cell-autonomous manner to mediate Nrg membrane localization. Together, these findings suggest that *Mcr* acts cell-autonomously, presumably as an integral membrane protein, to recruit SJ components or to maintain their localization at the lateral membrane of epithelial cells.

**Fig. 5. *Mcr* functions cell-autonomously to mediate Neuroglial membrane localization.** (A-C) Confocal section of *Mcr*<sup>K103</sup> embryo expressing UAS-*Mcr* (B, magenta in A) in epidermal stripes controlled by *hh-Gal4*. Nrg-YFP (C, green in A) is expressed in all epidermal cells. Note that *Mcr* protein does not spread away from the *hh-Gal4*-expressing cells and that Nrg-YFP membrane localization is rescued in a cell-autonomous manner only in the *Mcr*-expressing cells. Scale bars: 50 μm in A-C; 10 μm in A'-C'.

### SJ components are required for the correct localization of *Mcr*

We examined whether the localization of *Mcr* protein was also dependent on the presence of SJ components. We analyzed mutations in *megatrachea* (*mega*; *pickel* – FlyBase) (Behr et al., 2003), *sinuous* (*sinu*) (Wu et al., 2004), *Nrx-IV* and *Nrg* (Fig. 6; data not shown). Mutations in these core SJ components cause SJ protein mislocalization, loss of SJ structure and loss of barrier function. Cora was partially mislocalized basolaterally in *sinu*<sup>06524</sup> mutant salivary glands and hindguts (Fig. 6B',F') and uniformly mislocalized along lateral membranes in *Nrx-IV*<sup>4304</sup> and *Nrg*<sup>17</sup> salivary glands and hindguts (Fig. 6C',D',G',H'). Similarly, the distribution of *Mcr* extended basolaterally in *sinu*<sup>06524</sup> and *Nrx-IV*<sup>4304</sup> mutant epithelia. However, *Mcr* protein remained partially enriched apicolaterally even in cells in which Cora was uniformly mislocalized (Fig. 6F,G), suggesting that *Mcr* might localize partially independently of NrX-IV and Sinu. Strikingly, *Mcr* protein was strongly reduced in all epithelia in *Nrg*<sup>17</sup> mutant embryos, and residual *Mcr* protein localized to intracellular puncta (Fig. 6D,H; data not shown). Similarly, depletion of Nrg-YFP using anti-GFP nanobodies (Caussinus et al., 2011) in Nrg-YFP embryos caused loss of *Mcr* membrane staining in the nanobody-expressing cells (supplementary material Fig. S5). Thus, *Mcr* and Nrg mutually depend on each other for recruitment to, or maintenance at, the plasma membrane. Taken together, *Mcr* is required for the correct localization of SJ components and vice versa.

### *Mcr* is required during SJ assembly

To test whether *Mcr* mutations affect the assembly or maintenance of SJs, we monitored the distribution of the cytoplasmic SJ protein

**Fig. 6. The correct membrane localization of Mcr depends on SJ components.** Immunostaining of Mcr (A-H, green in merge A''-H'') and Cora (A'-H', magenta in merge) proteins in salivary glands (A-D) and hindguts (E-H) of stage 16 wild-type (A,E), *sinu*<sup>06524</sup> (B,F), *Nrx-IV*<sup>4304</sup> (C,G) and *Nrg*<sup>7</sup> (D,H) embryos. Cora is enriched at apicolateral membranes in the wild type, but extends basolaterally in *sinu*<sup>06524</sup> and *Nrx-IV*<sup>4304</sup> mutants, although Mcr remains partially enriched apically even in cells in which Cora is severely mislocalized (note the green apical Mcr signals in F'',G''). In *Nrg*<sup>7</sup> mutants, Mcr signals are dramatically reduced. Residual Mcr is detectable in intracellular puncta. Apical is up in E-H. Scale bars: 10 μm.

Cora and the integral membrane protein FasIII throughout SJ maturation in wild-type and in *Mcr*<sup>K103</sup> embryos (Fig. 7). In wild-type hindgut epithelia, Cora starts to localize at apicolateral membranes at stage 14 and subsequently extends basally during SJ maturation (Fig. 7A). By contrast, *Mcr*<sup>K103</sup> mutants show mislocalized Cora along the entire basolateral membrane from stage 14 (Fig. 7B). Similarly, FasIII was mislocalized from stage 14 in *Mcr*<sup>K103</sup> embryos (Fig. 7C,D). Consistent with these findings, *Mcr* embryos lack pSJs in the hindgut and in other ectodermal epithelia (Fig. 7E,F; data not shown). Together, these results suggest that Mcr is required for the initial assembly of SJ complexes, in agreement with our finding that Mcr membrane accumulation precedes the onset of Cora expression during stage 13, when SJs first form in the epidermis (supplementary material Fig. S3) (Tepass and Hartenstein, 1994).

#### Mcr is essential for epithelial barrier function

Finally, we asked whether Mcr is required for SJ-dependent epithelial barrier function. We observed that the levels of secreted

**Fig. 7. Mcr is required during SJ assembly.** (A-D) Confocal sections of embryonic hindguts stained for Cora (A,B) and FasIII (C,D). Apical is up in all panels. Embryonic stage is indicated. In *Mcr*<sup>K103/+</sup> heterozygous control embryos, Cora (A) and FasIII (C) localize at apicolateral membranes during stage 14 and continue to accumulate apicolaterally during subsequent stages (the basolateral front of accumulation is marked by arrowheads). In *Mcr*<sup>K103</sup> mutants, Cora (B) and FasIII (D) are not restricted to the apicolateral prospective SJ region at stage 14 but are instead distributed throughout the lateral plasma membrane. This distribution persists during subsequent stages. (E,F) Transmission electron microscopy sections of apicolateral membranes in hindgut cells of stage 17 embryos. Note that the ladder-like septa corresponding to pSJs in the wild type (E) are absent in *Mcr*<sup>K103</sup> mutants (F). Scale bars: 5 μm in A-D; 200 nm in E,F.

Serp-CBD-GFP protein in the tracheal lumen were reduced in *Mcr* embryos compared with controls. Instead, the protein became detectable in the hemocoel in *Mcr* mutants (Fig. 8A,B), suggesting that Serp-CBD-GFP is either not correctly secreted or that secreted Serp-CBD-GFP (33 kDa) is leaking across the tracheal epithelium. However, Serp-CBD-GFP did not accumulate inside tracheal cells in *Mcr* mutants (Fig. 8B), suggesting that the protein was not retained in the secretory pathway. We therefore probed epithelial barrier function in *Mcr* mutants by injecting Rhodamine-labeled dextran (10 kDa) into the hemocoel of stage 15 embryos (Lamb et al., 1998). In wild-type embryos fluorescent dextran was largely excluded from tracheal and hindgut lumina (Fig. 8C,E). By contrast, high levels of dextran were detectable inside the lumina of these organs in *Mcr*<sup>K103</sup> embryos 20 minutes after injection (Fig. 8D,F), indicating that the epithelial barrier was defective. The phenotype of *Mcr*<sup>K103</sup> embryos was comparable to that of *sinu* mutants, which lack functional SJs (Wu et al., 2004). Together, these results indicate that Mcr is essential for SJ-dependent epithelial barrier function. Leakage of luminal components, including Serp and Verm chitin deacetylases, across the tracheal epithelium might account for the tracheal tube size defects in *Mcr* mutants.

#### DISCUSSION

We describe a new and unexpected function of the complement-related protein Mcr in epithelial barrier formation. Insect TEPs are thought to function as secreted factors in innate immunity, although the functions of individual TEPs are not well understood (Blandin

**Fig. 8. *Mcr* is essential for epithelial barrier function.** (A,B) Confocal sections of living stage 15 wild-type (A) and *Mcr<sup>K103</sup>* mutant (B) embryos expressing Serp-CBD-GFP (CBD-GFP, green) in tracheal cells. Tracheal cell membranes are labeled by myristoylated RFP (myr-RFP, magenta). Note that luminal levels of Serp-CBD-GFP are lower in *Mcr* mutants than in the wild type. Conversely, Serp-CBD-GFP levels are elevated in the hemocoel (arrows in B) in *Mcr* mutants, suggesting that Serp-CBD-GFP is leaking across the tracheal epithelium in *Mcr* mutants. (C-F) Rhodamine-labeled 10 kDa dextran (magenta) was injected into stage 15 wild-type (C,E) and *Mcr<sup>K103</sup>* mutant (D,F) embryos expressing GFP in tracheal cells (green). Dextran is largely excluded from the tracheal (C) and hindgut (E) lumen in wild-type embryos, but strongly accumulates 20 minutes after injection inside the lumen of *Mcr* mutant tracheae (D) and hindguts (F). The basal surface of the hindgut is outlined (dashed line in E,F). Scale bars: 10  $\mu$ m.

and Levashina, 2004; Bou Aoun et al., 2011). We found that *Mcr*, a member of the diverged Tep6 subfamily, is a membrane-localized protein required for the assembly of SJs. This conclusion is based on three lines of evidence. First, we show that *Mcr* protein localizes at the lateral membrane of epithelial cells, where its distribution overlaps with that of known SJ components. Second, loss of *Mcr* function leads to morphological, ultrastructural and epithelial barrier defects resembling those of mutants lacking SJ components. This finding explains why mutations in *Mcr*, unlike other TEP genes, cause embryonic lethality (Bou Aoun et al., 2011). Third, *Mcr* is required in a cell-autonomous fashion for the correct assembly of SJ proteins at apicolateral membranes, and, conversely, SJ components are required for the correct membrane localization of *Mcr*.

Our finding that *Mcr* protein localizes at the plasma membrane and does not spread away from the producing cells suggests that full-length *Mcr* is an integral membrane protein, presumably anchored in the membrane by its predicted transmembrane domain. This notion is further substantiated by the recent mass spectrometry-based identification of *Mcr* along with several membrane-associated SJ proteins as components of the Claudin complex (Jaspers et al., 2012). However, earlier work had shown that *Mcr* is secreted by S2 cells into the culture medium (Stroschein-Stevenson et al., 2006). We were not able to detect secreted *Mcr* protein in the embryonic hemocoel or in tubular organ lumina, suggesting that the majority of *Mcr* protein is stably associated with the plasma membrane. However, secreted *Mcr* protein species might be present at low concentrations and may be poorly immobilized by chemical fixation, whereas the membrane-bound locally concentrated pool of the protein is readily detected by immunofluorescence. Consistent with this view, localized *Mcr* signals become visible only after the onset of zygotic *Mcr* expression, although *Mcr* protein of presumably

maternal origin is detectable by immunoblot throughout embryogenesis. These results and the presence of multiple *Mcr*-specific bands on immunoblots suggest that *Mcr* protein is processed into different cleavage products. Proteolytic cleavage may yield *Mcr* isoforms lacking the C-terminal transmembrane domain. Such *Mcr* cleavage products may be released from the plasma membrane through proteolytic shedding. Indeed,  $\alpha$ 2M proteins are proteolytically processed by attacking proteases, which are subsequently inhibited through covalent thioester bond formation with the  $\alpha$ 2M protein (Borth, 1992). The protease bait region is expected to render *Mcr* sensitive to protease cleavage, although attacking proteases are presumably not inactivated due to the mutated thioester motif. Thus, proteolytic processing of *Mcr* may result in multiple secreted and membrane-bound protein isoforms, which could carry out distinct functions. Secreted *Mcr* protein was shown to mediate opsonization of *C. albicans* cells and to promote their uptake by S2 cells in tissue culture (Stroschein-Stevenson et al., 2006). Secreted *Mcr* isoforms might play a similar role in pathogen clearance by hemocytes *in vivo*. Conversely, we show that membrane-localized *Mcr* is involved in SJ assembly and epithelial barrier function. Our finding that *Mcr* is required autonomously in tracheal cells suggests that integral membrane isoforms, rather than secreted *Mcr* protein, mediate tracheal tube size control and epithelial barrier function. However, these results do not formally exclude an autocrine requirement of secreted *Mcr* protein in tracheal cells.

The presence of *Mcr* in embryonic germ cells prompted us to test whether *Mcr* plays a role in gonad development. Although we did not detect defects in embryonic germ cell migration and gonad coalescence in zygotic *Mcr* mutants (data not shown), potential functions of *Mcr* in these processes might be masked by maternal *Mcr* gene products in the embryo. However, we found *Mcr* to be essential in the female germline for oogenesis, thus precluding the analysis of *Mcr* mutant germline clones.

The dynamics of SJ formation and the order of assembly of SJ components are not well understood. Our results suggest that *Mcr* plays an early role during SJ assembly at the lateral plasma membrane. Such a role is consistent with our finding that *Mcr* membrane accumulation precedes the accumulation of Cora at epidermal cell membranes. Mutations in all known SJ components cause mislocalization of all other components of the complex, indicating a high degree of mutual interdependence between SJ proteins (Ward et al., 1998; Oshima and Fehon, 2011). Similarly, we showed that *Mcr* is required for the correct localization of SJ components, and that *Mcr* localization depends on core SJ components. Furthermore, we found the immunoglobulin and fibronectin domain-containing transmembrane protein Nrg to be essential for maintaining membrane localization or stability of *Mcr* protein. Nrg might bind to the extracellular part of *Mcr* and thereby protect it from proteolytic cleavage. Alternatively, Nrg could be required at the transcriptional or translational level for *Mcr* expression. However, the abnormal punctate distribution of residual *Mcr* protein in *Nrg* mutants suggests that Nrg is required post-translationally, rather than for *Mcr* mRNA or protein synthesis. Although it is not yet clear whether *Mcr* and Nrg interact directly, the strict mutual dependency between the two proteins suggests that they act together to mediate an essential early step in SJ assembly. We speculate that *Mcr* might interact with other SJ-associated proteins, including Nrg, through its extracellular domain, because the small (15 amino acid) cytoplasmic domain of *Mcr* is not conserved among insects and lacks identifiable protein-binding motifs, such as the PDZ consensus binding sites that are found in several SJ components, including Gliotactin, Nrg, Nrx-

IV and the Claudins. The identification of binding partners of Mcr will be instrumental for understanding the molecular hierarchy of the SJ assembly pathway.

The discovery of a Macroglobulin complement-related protein as a component of SJs was surprising, since  $\alpha$ 2M proteins have generally been thought of as secreted factors involved in innate immunity, and functions of  $\alpha$ 2M as epithelial cell surface proteins have to our knowledge not been described thus far. *Anopheles* Tep1, which is the best-studied insect TEP, binds to bacteria and *Plasmodium* cells and targets them for phagocytosis (Levashina et al., 2001; Blandin and Levashina, 2004; Blandin et al., 2008). *Drosophila* Tep2 and Tep3 are required for phagocytosis by S2 cells of *E. coli* and *Staphylococcus aureus*, respectively, and Mcr is specifically required for phagocytosis of *C. albicans* (Stroschein-Stevenson et al., 2006). Our finding that Mcr is a cell surface protein required for epithelial barrier formation has potential implications for the evolution and function of occluding cell-cell junctions. SJs not only serve as a paracellular diffusion barrier, but they also prevent pathogens from crossing epithelial barriers and invading the organism. Mcr as a complement-like protein may therefore be strategically well placed on epithelial cell surfaces to provide a first line of defense against invading pathogens. This might be particularly relevant also for the gonads, where Mcr protein localizes on germ cell membranes. Interestingly, the process of pathogen encapsulation by hemocytes in insects involves the formation of SJ-like structures (Gupta and Han, 1988; Russo et al., 1996). Larger pathogens, such as parasitoid wasp eggs, are recognized by plasmatocytes and lamellocytes, which attach to and spread around the wasp egg, thus separating the pathogen from the hemocoel and enabling melanization of the capsule. This process involves the formation of an epithelial-like layer of multiple plasmatocytes surrounding the capsule (Russo et al., 1996). Interestingly, the encapsulating plasmatocytes are connected by SJs, which contain Cora and Nrg (Russo et al., 1996; Williams, 2009). Although this process has not been characterized in detail, it is likely that additional SJ components, possibly including Mcr, are involved in the formation of cell-cell junctions between immune cells. SJ-like structures were also observed between mammalian lymphocytes and macrophages upon encapsulation of pathogens (McIntyre et al., 1976; Siebert, 1979). These findings suggest an intriguing link between innate immunity and the formation of occluding cell-cell junctions. It is tempting to speculate whether mammalian CD109, a GPI-linked cell surface glycoprotein of the  $\alpha$ 2M family found on a subset of hematopoietic and myoepithelial cells (Hasegawa et al., 2007), might play similar roles to Mcr in *Drosophila*. Although the function of CD109 is largely unknown, it will be interesting to explore whether membrane-bound  $\alpha$ 2M proteins mediate functions in epithelial barrier formation and innate immunity in vertebrates and invertebrates.

## MATERIALS AND METHODS

### *Drosophila* strains and genetics

Fly stocks are described in FlyBase unless mentioned otherwise: *w<sup>1</sup>*, *Abd-B-Gal4* 199 (de Navas et al., 2006), *btl-Gal4* (Shiga et al., 1996), *hh-Gal4*, *UAS-lacZ<sup>RNAi</sup>* (gift from Peter Gallant, University of Würzburg, Germany), *UAS-dicer2* (VDRC 60014), *UAS-Mcr<sup>RNAi</sup>* (VDRC 100197), *UAS- $\alpha$ -Cat-GFP* (Oda and Tsukita, 1999), *UAS-mCherry-NLS* (Cauissinus et al., 2008), *UAS-Serp-CBD-GFP* (Luschnig et al., 2006), *UAS-myr-tdTomato* (Bloomington 32223), *UAS-NSlmb-vhhGFP4* (Cauissinus et al., 2011), *Df(2L)Exel7034* (Bloomington 7807), *Mcr<sup>EY07421</sup>* (Bellen et al., 2004), *mega<sup>G0012</sup>* (Bloomington 11471), *Nrg<sup>17</sup>* (Bloomington 5595), *Nrx-IV<sup>4304</sup>* (Bloomington 4380), *sinu<sup>06524</sup>* (Bloomington 11690), *Scrib-GFP*, *Nrx-IV-GFP* (Buszczak et al., 2007) and *Nrg-YFP* (DGRC 115188). *Mcr* mutations

were induced by ethylmethanesulfonate (EMS) mutagenesis of a *btl-Gal4 UAS-GFP UAS-Verm-RFP* chromosome (Förster et al., 2010) and recombined onto FRT40A chromosomes. The *luf/Mcr* locus was mapped to 28E1-E5 by non-complementation of *Df(2L)Trf-C6R31* and *Df(2L)Exel7034* and by complementation of *Df(2L)TE29Aa-11*. For tracheal-specific RNAi, UAS-RNAi transgenes and UAS-*dicer2* were co-expressed using *btl-Gal4*.

### Molecular biology

Genomic DNA was extracted from 20 homozygous *Mcr* embryos [identified by the absence of *CyO Dfd-YFP* (Le et al., 2006)] for each *Mcr* allele. The *Mcr* coding sequence, including exon-intron boundaries, was amplified from *Mcr* mutants and from the parental strain. PCR products were sequenced on both strands. UAS-Mcr was generated by amplifying the *Mcr* coding sequence from the *Mcr* full-length cDNA LD23292 (BDGP) using oligonucleotides (5'-3', restriction sites are underlined): EcoRI-Mcr-F, ATATGAATTCGAGCAATGATGTGGCACTTGC; and NotI-Mcr-R, TATAGCGGCCCGCCCTGTGAGCAGTTGCATCATGT. The fragment was inserted between the *EcoRI* and *NotI* sites of pUASTattB (Bischof et al., 2007). The construct was integrated into the attP2 site at 68A4 using  $\Phi$ C31 integrase (Bischof et al., 2007).

### In situ hybridization

A 937 bp fragment containing the *Mcr* 3'UTR was amplified from genomic DNA using oligonucleotides containing the T7 RNA polymerase promoter either on the forward or reverse primer. PCR products were used as templates for *in vitro* transcription. Antisense and sense RNA probes were generated using digoxigenin-labeled UTP (Roche) and were detected using alkaline phosphatase-conjugated anti-digoxigenin Fab fragments (1:2000; Roche).

### Immunofluorescence

Embryos were fixed in 4% formaldehyde in PBS/heptane for 20 minutes and devitellinized by shaking in methanol/heptane or ethanol/heptane (for anti-E-Cad immunostainings). The following antibodies were used: chicken anti-GFP (1:500; Abcam, ab13970), mouse anti-GFP (1:300; Clontech, JL8), rabbit anti-Mcr [1:1000; gift from A. Johnson, UCSF (Stroschein-Stevenson et al., 2006)], guinea pig anti-Cora [1:200 (Lamb et al., 1998)], mouse anti-Dlg (1:500; 4F3, DSHB), mouse anti-FasIII (1:50; 7G10, DSHB), mouse anti- $\alpha$ -Spec (1:50; 3A9, DSHB), guinea pig anti-Uif [1:1000 (Zhang and Ward, 2009)] and rat anti-DE-Cad (1:100; DCAD2, DSHB). Goat secondary antibodies were conjugated with Alexa 405, Alexa 488, Alexa 568 (Molecular Probes) or Cy5 (Jackson ImmunoResearch). Chitin was detected using Alexa Fluor-SNAP-tagged chitin-binding domain from *Bacillus circulans* chitinase A1, which was prepared as previously described (Caviglia and Luschnig, 2013).

### Tissue culture

S2R+ cells were cultured on glass coverslips in Schneider's medium at 25°C. Cells were transfected with pUASTattB-Mcr using FuGene HD reagent (Promega). Forty-eight hours after transfection, cells were fixed with 4% formaldehyde/PBS and stained with anti-Mcr (Stroschein-Stevenson et al., 2006) and Hoechst 33342.

### Light microscopy and image analysis

Imaging was performed using an Olympus FV1000 confocal microscope with 40 $\times$ /1.3 NA and 60 $\times$ /1.35 NA objectives. Images were processed using Huygens Deconvolution (SVI), ImageJ (v1.42), Imaris (v7.3.0; Bitplane) and Adobe Photoshop. For live imaging, embryos were dechorionated, mounted on glue-coated coverslips and covered with Voltalef 10S oil. The three-dimensional path of the DT lumen and apical cell outlines were traced using Imaris. Luminal length was measured in living embryos between fusion joints of DT metamerites Tr5/6 and Tr8/9. *P*-values were calculated using Student's two-tailed, unpaired *t*-test.

### Electron microscopy

Dechorionated stage 17 embryos were high-pressure frozen (Leica EM HPM100) and freeze-substituted (Leica EM AFS2) in 1% OsO<sub>4</sub> in water-free acetone. Subsequently, embryos were block-stained in 1% uranyl

acetate in water-free acetone for 1 hour at 4°C and embedded in Epon/Araldite (Sigma). Ultra-thin (50–70 nm) transverse sections of posterior abdominal segments were post-stained with lead citrate and imaged in an FEI Tecnai G2 Spirit transmission electron microscope.

### Immunoblotting

Embryos were homogenized in Laemmli buffer. Equivalents of ten embryos per lane were loaded on 7.5% polyacrylamide SDS-PAGE gels. Proteins were transferred to nitrocellulose membranes by electroblotting. Membranes were probed with rabbit anti-Mcr [1:1000 (Stroschein-Stevenson et al., 2006)], mouse anti- $\alpha$ -Tubulin (1:50,000; Sigma, DM1A) and guinea pig anti-Verm [1:2500 (Wang et al., 2006)].

### Dextran injections

Rhodamine-labeled 10 kDa dextran (Molecular Probes) was injected as described (Lamb et al., 1998) into wild-type and *Mcr*<sup>K103</sup> embryos carrying *btl-Gal4 UAS-GFP*. Embryos were imaged 20 minutes after injection.

### Acknowledgements

We are indebted to Kristina Armbruster and Stefanie Limmer, who isolated the *Mcr* mutants. We thank Markus Affolter, Emmanuel Caussinus, Rick Fehon, Peter Gallant, Alexander Johnson, Reinhard Schuh, Robert Ward, Ryohei Yagi, the Bloomington *Drosophila* Stock Center and the Developmental Studies Hybridoma Bank for providing fly stocks and reagents; Ursula Lüthi and Andres Kaech at the Center for Microscopy and Image Analysis, University of Zurich, for providing expert support with electron microscopy sample preparation and imaging; Robert Ward for helpful comments and for sharing unpublished information; and Dominique Ferrandon and Anne Uv for comments on the manuscript. We are indebted to Christian Lehner for continuous support and discussions.
